INTRODUCTION

Inkjet printing is a mature technology for colorful graphic arts. It excels at customized, large-area, high-resolution, and small-volume production. With the developments in conductive, dielectric, and even semi-conducting inks, there is potential for large-area inkjet electronics fabrication. Passive radio frequency devices can benefit greatly from a printing process, seeing as the size of these devices is defined by the frequency of operation. The large size of radio frequency passives means that they either take up expensive space on chip, or are fabricated on a separate substrate layer cost higher than the chip itself, and are then bonded to the chip. This has hindered cost-sensitive high volume applications such as radio frequency identification tags. While much work has been undertaken on inkjet-printed conductors and inductors for passive antennas and filters on microwave substrates and even paper, little work has been done on the printing of the dielectric materials aimed at radio frequency passives.

Both the conductor and dielectric needs to be integrated to create a multilayer inkjet printing process that is capable of making quality passives like such as capacitors and inductors. Three inkjet-printed dielectrics are investigated in this thesis: a ceramic (alumina), a thermal-cured polymer (poly 4 vinyl phenol), and a UV-cured polymer (acrylic based). Both a silver nanoparticle ink and a custom in-house formulated particle-free silver ink are explored for the conductor. The focus is on passives, mainly capacitors and inductors. Compared to low frequency electronics, radio frequency components have additional sensitivity with regard to skin depth of the conductor and surface roughness, as well as dielectric constant and loss tangent of the dielectric. These issues are investigated with the aim of making the highest quality components possible and to understand the current limitations of inkjet-fabricated radio frequency devices.
